The Radiovision Electronic Network viewing system is a video-enhanced AM stereo transmitter that allows a station to broadcast both audio and still-picture video information. It takes full motion video and converts it to one minute snapshots over the air. No special equipment is necessary other than a slow-scan converter. On the receiving end, two radios are necessary - one to receive the audio in normal fashion and another (which is tuned slightly to the left of the station) to pick up picture data and send it to the scan converter via the headphone jack. This allows listeners to view pictures on the scan converter as they listen to audio.
